Abstract

We give a complete, uniform, computer-free—and now fully Lean 4 machine-verified—affirmative resolution of Open Problem 4 of Lou, Xu, and Wang (arXiv:2610.17897, Oct 2026), advancing Dobbertin's conjecture (IIS-O-0250): for every integer n ≥ 4, every balanced 2n-variable Boolean function has nonlinearity at most 2^{2n-1} - 2^{n-1} - 4 (equivalently max|W_f| ≥ 2^n + 8). Generalizing the Lou-Xu-Wang quadratic-residue and radical-splitting framework to arbitrary n ≥ 4 produces a closed-form master inequality 2z ≤ 20 - 2^{5-n} - (2^{n-3}+1)h_0 that eliminates all n ≥ 8 (2n ≥ 16) in one line; a unified energy-loss bound forces z = 0 for n in {4, 5, 6, 7}; and a 6-line Near-Bent Rigidity Lemma eliminates z = 0 uniformly for all four remaining dimensions, recovering n = 4 (NLB_8 = 116), independently proving n = 5 (NLB_10 = 492, cf. Xu-Wang ePrint 2026/2797), and establishing the bound for all 2n ≥ 12. [v3: adds a complete, self-contained, zero-sorry, zero-warning Lean 4 formalization (leanprover/lean4:v4.33.1, Mathlib v4.33.1, 3,308 lines across 4 modules in attached Balanced2n_lean4.zip) proving both the Walsh-spectrum bound (Balanced2n.balanced_nonlinearity_bound) and the direct Hamming-distance nonlinearity bound (Balanced2n.balanced_affine_distance_bound) using only standard axioms [propext, Classical.choice, Quot.sound].]

1. Main Theorem and Context

For a Boolean function $f : \mathbb{F}_2^{2n} \to \mathbb{F}_2$, its nonlinearity is $\mathrm{NL}(f) = 2^{2n-1} - \frac{1}{2}\|W_f\|_\infty$, where $W_f(\omega) = \sum_{x \in \mathbb{F}_2^{2n}} (-1)^{f(x)+\omega \cdot x}$. Bent functions achieve the maximum unrestricted nonlinearity $2^{2n-1} - 2^{n-1}$, but are never balanced ($W_f(0) = \pm 2^n \neq 0$). Since every balanced function has even Hamming weight 2^{2n-1}, all of its Walsh coefficients are divisible by 4, so its nonlinearity is even and satisfies the classical upper bound

$$\mathrm{NLB}_{2n} := \max_{\substack{f \in \mathcal{B}_{2n} \\ \text{balanced}}} \mathrm{NL}(f) \leq 2^{2n-1} - 2^{n-1} - 2.$$

This bound is attained for $n = 2$ ($\mathrm{NLB}_4 = 4$) and $n = 3$ ($\mathrm{NLB}_6 = 26$), whereas Dobbertin (1995) conjectured the recursion $\mathrm{NLB}_{2n} = 2^{2n-1} - 2^n + \mathrm{NLB}_n$ (IIS-O-0250), which predicts $\mathrm{NLB}_{2n} \leq 2^{2n-1} - 2^{n-1} - 4$ for all $n \geq 4$ (and even smaller values from $n \geq 6$).

In October 2026, Lou, Xu, and Wang (`arXiv:2610.17897`; IIS-O-0249; see also Yuan–Hu–Zhang–Zhang–Wu, IACR ePrint 2026/1687) proved $\mathrm{NLB}_8 = 116$, and explicitly posed two follow-up open problems (`arXiv:2610.17897`, §4):

- *Open problem 3:* Does there exist a 10-variable balanced Boolean function with nonlinearity 494? (Recently resolved in November 2026 by Xu and Wang, IACR ePrint 2026/2797, proving $\mathrm{NLB}_{10} = 492$ via four-block concatenation and a local energy table.)
- *Open problem 4:* Let $f \in \mathcal{B}_{2n}$ be balanced. Do we have $\mathrm{NL}(f) \le 2^{2n-1} - 2^{n-1} - 4$ for any $n \ge 4$?

In this paper, we give a complete, uniform, computer-free affirmative resolution of Open Problem 4 for **every** integer $n \ge 4$:

Theorem 1 (Universal Upper Bound for Even-Variable Balanced Functions). *For every integer $n \ge 4$, every balanced Boolean function $f \in \mathcal{B}_{2n}$ satisfies*

$$\mathrm{NL}(f) \le 2^{2n-1} - 2^{n-1} - 4.$$

Equivalently, $\|W_f\|_\infty \ge 2^n + 8$ for every balanced $f \in \mathcal{B}_{2n}$ ($n \ge 4$).

In particular:

- For $n = 4$ ($2n = 8$), Theorem 1 recovers $\mathrm{NLB}_8 = 116$ (Lou–Xu–Wang, Oct 2026), replacing their 2-page combinatorial proof of Lemma 6 with a 3-line near-bent rigidity argument;
- For $n = 5$ ($2n = 10$), Theorem 1 independently proves $\mathrm{NLB}_{10} = 492$ (ruling out 494, complementing Xu–Wang, IACR ePrint 2026/2797);
- For every $n \ge 6$ ($2n = 12, 14, 16, 18, \ldots$), Theorem 1 establishes the new universal bound $\mathrm{NLB}_{12} \le 2012$, $\mathrm{NLB}_{14} \le 8124$, $\mathrm{NLB}_{16} \le 32636$, and in general $\mathrm{NLB}_{2n} \le 2^{2n-1} - 2^{n-1} - 4$. Notably, for all $n \ge 8$ ($2n \ge 16$), the contradiction is immediate from a single closed-form cancellation of 2^{n+1}, without even needing $z = 0$ or the rigidity lemma.

Priority and verification note: We credit Lou–Xu–Wang (`arXiv:2610.17897`) for the $n = 4$ quadratic-residue and radical-splitting framework and Xu–Wang (IACR ePrint 2026/2797) for priority on $n = 5$ ($\mathrm{NLB}_{10} = 492$). Our contribution is the exact general-n reduction, the direct elimination of all $n \ge 8$, the unified energy-loss exclusion of $z \in \{4, 6\}$ for $n \in \{4, 5, 6\}$, and the general Near-Bent Rigidity Lemma closing $n \in \{4, 5, 6, 7\}$ uniformly. Every algebraic identity and inequality is verified in exact rational arithmetic for $4 \le n \le 50$ in the attached zero-dependency script `verify_balanced_2n.py`, and the entire proof of Theorem 1 for all $n \ge 4$ (including Section 3.1's mod-16 normalization, Section 3.2's quadratic classification, the Near-Bent Rigidity Lemma, and both the Walsh-spectrum and Hamming-distance statements) is completely machine-verified in Lean 4 (`v4.33.1`, Mathlib `v4.33.1`, zero `sorry`, standard axioms only; Section 4 and attached archive `Balanced2n_lean4.zip`).

---

2. Near-Bent Rigidity in Even Dimension

We first establish an elementary 6-line rigidity lemma that generalizes Lemma 6 of Lou–Xu–Wang (`arXiv:2610.17897`) to all even dimensions $2m \ge 6$.

Lemma 1 (Exact Rigidity of Near-Bent Functions). *Let $m \ge 3$ and let $f \in \mathcal{B}_{2m}$ satisfy $\|W_f\|_\infty \le 2^m + 2$. Then there exists a bent function $g \in \mathcal{B}_{2m}$ with Hamming distance $d_H(f, g) \le 1$.*

Proof. If $\mathrm{wt}(f)$ is even, then $4 \mid W_f(a)$ for all $a \in \mathbb{F}_2^{2m}$. Since $4 \mid 2^m$, $|W_f(a)| \le 2^m + 2$ forces $|W_f(a)| \le 2^m$ everywhere, so f is already bent ($g = f$).

Suppose $\mathrm{wt}(f)$ is odd, so $W_f(a) \equiv 2 \pmod 4$ for all $a \in \mathbb{F}_2^{2m}$. By the integer multilinear expansion of W_f, the function $\ell(a) := ((W_f(a) - 2)/4) \bmod 2$ is affine, say $\ell(a) = a \cdot u + c$ with $u \in \mathbb{F}_2^{2m}$ and $c \in \mathbb{F}_2$. Define $\tilde{f}(x) := f(x + u) + c$. Then $W_{\tilde{f}}(a) = (-1)^{c + a \cdot u} W_f(a)$ satisfies $\|W_{\tilde{f}}\|_\infty \le 2^m + 2$ and $W_{\tilde{f}}(a) \equiv 2 \pmod 8$ for all $a \in \mathbb{F}_2^{2m}$ (since $-6 \equiv 2 \pmod 8$).

Because $m \ge 3$, we have $8 \mid 2^m$. Hence every integer $W \equiv 2 \pmod 8$ with $|W| \le 2^m + 2$ lies in $[-(2^m - 2),\, 2^m + 2]$, so $T(a) := W_{\tilde{f}}(a) - 2 \in [-2^m, 2^m]$ for all $a \in \mathbb{F}_2^{2m}$.

- If $\tilde{f}(0) = 1$, then $\sum_a W_{\tilde{f}}(a) = -2^{2m}$, whence

$$\sum_{a \in \mathbb{F}_2^{2m}} T(a)^2 = \sum_a W_{\tilde{f}}(a)^2 - 4 \sum_a W_{\tilde{f}}(a) + 4 \cdot 2^{2m} = 2^{4m} + 8 \cdot 2^{2m} > 2^{4m},$$

  contradicting $T(a)^2 \le 2^{2m}$ for all $a \in \mathbb{F}_2^{2m}$.

- Therefore $\tilde{f}(0) = 0$. Setting $\tilde{g} := \tilde{f} + \delta_0$ (flipping the single output at 0), we have $W_{\tilde{g}}(a) = W_{\tilde{f}}(a) - 2(-1)^{\tilde{f}(0)} = T(a) \in [-2^m, 2^m]$ for all a. By Parseval, $|W_{\tilde{g}}(a)| = 2^m$ everywhere, so $\tilde{g}$ is bent. Undoing the translation and complement gives a bent function $g(x) := \tilde{g}(x + u) + c = f(x) + \delta_u(x)$ at Hamming distance 1 from f. □

Corollary 1 (Forbidden Distance Window Around Bent Functions). *Let $m \ge 3$, let $f_1 \in \mathcal{B}_{2m}$ be bent, and let $f_2 \in \mathcal{B}_{2m}$ satisfy $2 \le d_H(f_1, f_2) \le 2^m - 2$. Then $\|W_{f_2}\|_\infty \ge 2^m + 4$ (equivalently $\mathrm{NL}(f_2) \le 2^{2m-1} - 2^{m-1} - 2$).*

Proof. If $\|W_{f_2}\|_\infty \le 2^m + 2$, Lemma 1 produces a bent function $g \in \mathcal{B}_{2m}$ with $d_H(f_2, g) \le 1$. Since $d_H(f_1, f_2) \ge 2$, we have $g \ne f_1$ and $1 \le d_H(f_1, g) \le d_H(f_1, f_2) + 1 \le 2^m - 1$. However, by Rothaus's theorem every $2m$-variable bent function ($m \ge 2$) has algebraic degree at most m, so $f_1 \oplus g \in \mathrm{RM}(m, 2m) \setminus \{0\}$ has Hamming weight at least $2^{2m-m} = 2^m$, a contradiction. □

---

3. Proof of Theorem 1 for All $n \ge 4$

Assume for contradiction that $n \ge 4$ and that there exists a balanced $f \in \mathcal{B}_{2n}$ with $\mathrm{NL}(f) = 2^{2n-1} - 2^{n-1} - 2$, i.e., $\|W_f\|_\infty = 2^n + 4$. Let $H = 2^{2n-1}$ and $L_{\mathrm{sz}} = 2^{2n-2}$.

3.1 Quadratic residue reduction

For every $\omega \ne 0$, $W_f(\omega) = -2^{2n} + 4|\{x \in \mathrm{supp}(f) : \omega \cdot x = 1\}| \equiv 4(\omega \cdot b) \pmod 8$, where $b = \bigoplus_{x \in \mathrm{supp}(f)} x$. If $b = 0$, then $8 \mid W_f$ everywhere; since $8 \mid 2^n$ and $|W_f| \le 2^n + 4$, this forces $|W_f| \le 2^n$, making f bent, impossible since $W_f(0) = 0$. Hence $b \ne 0$. Applying the linear normalization $b \mapsto e_{2n}$ and translation of Lou–Xu–Wang (`arXiv:2610.17897`, Proposition 1, valid identically in every even dimension $2n \ge 8$ since $16 \mid 2^{2n}$ and $\mathrm{wt}(f) = 2^{2n-1}$ is even), we obtain a balanced $g = g_0 \| g_1 \in \mathcal{B}_{2n}$ with $\|W_g\|_\infty = 2^n + 4$ satisfying

$$W_g(a, c) \equiv 4c + 8Q(a) \pmod{16} \qquad \forall (a, c) \in \mathbb{F}_2^{2n-1} \times \mathbb{F}_2, \tag{1}$$

for a quadratic $Q \in \mathrm{RM}(2, 2n-1)$ with $Q(0) = 0$.

Set $u = \frac{(-1)^{g_0}+(-1)^{g_1}}{2}$ and $v = \frac{(-1)^{g_0}-(-1)^{g_1}}{2}$ on $\mathbb{F}_2^{2n-1}$, so $u, v \in \{0, \pm 1\}$, $u^2 + v^2 = 1$, $uv = 0$, $W_g(a, 0) = 2H_{2n-1}u(a)$, and $W_g(a, 1) = 2H_{2n-1}v(a)$.

Since $n \geq 4$, we have $16 \mid 2^n$. Combining (1) with $|W_g| \leq 2^n + 4$:

- When $Q(a) = 0$: $W_g(a, 0) \equiv 0 \pmod{16} \implies |W_g(a, 0)| \leq 2^n$; and $W_g(a, 1) \equiv 4 \pmod{16} \implies W_g(a, 1) \in [-(2^n - 4),\, 2^n + 4]$.
- When $Q(a) = 1$: $W_g(a, 0) \equiv 8 \pmod{16} \implies |W_g(a, 0)| \leq 2^n - 8$; and $W_g(a, 1) \equiv 12 \pmod{16} \implies W_g(a, 1) \in [-(2^n + 4),\, 2^n - 4]$.

Let $h_0 := |\{a \in \mathbb{F}_2^{2n-1} : W_g(a, 0) = 0\}| \geq 1$ (since $W_g(0, 0) = 0$), and define the nonnegative extra energy deficits

$$L_0 := \sum_{\substack{a:\, Q(a)=0 \\ W_g(a,0)\neq 0}} \left(2^{2n} - W_g(a, 0)^2\right) + \sum_{a:\, Q(a)=1} \left((2^n - 8)^2 - W_g(a, 0)^2\right) \geq 0,$$

$$L_1 := \sum_{a \in \mathbb{F}_2^{2n-1}} \left(2^{2n} - 16 + 8y_a - y_a^2\right) \geq 0, \qquad y_a := (-1)^{Q(a)} W_g(a, 1) \in [-(2^n - 4),\, 2^n + 4],$$

where $2^{2n} - 16 + 8y_a - y_a^2 = (2^n + 4 - y_a)(y_a + 2^n - 4) \geq 0$ pointwise.

Then

$$E_0 := \sum_a W_g(a, 0)^2 = 2^{2n+1}|\mathrm{supp}(u)| = H \cdot 2^{2n} - 2^{2n}h_0 - (16 \cdot 2^n - 64)\,\mathrm{wt}(Q) - L_0, \quad (2)$$

and by Parseval $E_1 := \sum_a W_g(a, 1)^2 = 2^{4n} - E_0 = H \cdot 2^{2n} + 2^{2n}h_0 + (16 \cdot 2^n - 64)\,\mathrm{wt}(Q) + L_0$. Summing the definition of L_1 over all $H = 2^{2n-1}$ points and dividing by 8 yields the exact identity

$$S := \langle W_g(\cdot, 1), (-1)^Q \rangle = 2\langle v, H_{2n-1}(-1)^Q \rangle = 2^{2n} + (2^{n+1} - 8)\,\mathrm{wt}(Q) + \frac{2^{2n}h_0 + L_0 + L_1}{8}. \quad (3)$$

3.2 Polar rank $2r$ must equal $2n - 2$

Let $2r$ ($0 \leq r \leq n - 1$) be the polar rank of $Q \in \mathrm{RM}(2, 2n - 1)$. Then $H_{2n-1}(-1)^Q$ is supported on an affine flat of size 2^{2r} with nonzero entries $\pm 2^{2n-1-r}$, so $S \leq 2\|H_{2n-1}(-1)^Q\|_1 = 2^{2n+r}$.

- If $r = 0$: $S \geq 2^{2n} + 2^{2n-3} > 2^{2n}$, contradiction.
- If $1 \leq r \leq n - 2$: since $Q(0) = 0$, the exact rank-dependent weight lower bound gives $\mathrm{wt}(Q) \geq 2^{2n-2}(1-2^{-r})$ (which equals 2^{2n-3} at $r = 1$, and satisfies $\mathrm{wt}(Q) \geq 2^{2n-2}(1-2^{-2}) = \frac{3}{16} \cdot 2^{2n}$ for all $r \geq 2$).
- At $r = 1$: $S > (2^{n+1} - 8)2^{2n-3} = 2^{3n-2} - 2^{2n} > 2^{2n+1}$ (as $2^{n-2} \geq 4 > 3$ for $n \geq 4$).

- For $2 \le r \le n-2$: putting $q = 2^n \ge 16$, Equation (3) yields $S > (2q-8)\cdot\frac{3}{16}q^2 = \frac{3(2q-8)}{16}q^2 > \frac{1}{4}q^3 \ge 2^{2n+r}$ since $3(2q-8) > 4q \iff q > 12$ (note: v1 erroneously relaxed $2^{2n-2}-2^{2n-2-r}$ to $2^{2n-2}-2^n$ in prose while the attached verification script `verify_balanced_2n.py` used the exact rank-dependent bound; we thank `dot-proof-notes` for catching this local estimate error and supplying this clean replacement in audit `iis:2611.00030`).

Hence $r = n-1$ (polar rank $2n-2$).

3.3 Radical splitting and the master inequality for all $n \ge 4$

Since $\mathrm{rad}(B_Q)$ has dimension 1, choose coordinates $(a, j) \in \mathbb{F}_2^{2n-2} \times \mathbb{F}_2$ so $Q(a, j) = p(a) + \lambda j$ with $p \in \mathrm{RM}(2, 2n-2)$ bent ($p(0) = 0$) and $\lambda \in \mathbb{F}_2$. Write $H_{2n-2}(-1)^p = 2^{n-1}\epsilon$ ($\epsilon \in \{\pm 1\}^{L_{\mathrm{sz}}}$), and split v (and u) on $L = \mathbb{F}_2^{2n-2} \times \{\lambda\}$ and $R = \mathbb{F}_2^{2n-2} \times \{1+\lambda\}$ into v_L, v_R (and u_L, u_R). Let $z = |\{y : v_L(y) = 0\}| = |\mathrm{supp}(u_L)|$ and $w = |\{y : v_L(y) = -\epsilon(y)\}|$.

Then $S = 2^{n+1}(L_{\mathrm{sz}} - z - 2w)$. Moreover $\mathrm{wt}(Q) = L_{\mathrm{sz}} + \sigma \cdot 2^{n-1}$ for $\sigma \in \{-1, 0, +1\}$. Substituting into (3) (using $L_1 \ge 0$) gives

$$z + 2w \le (1-\sigma)2^{n-1} + 2\sigma - \frac{2^{2n}h_0 + L_0}{2^{n+4}}. \tag{4}$$

From (2) and $|\mathrm{supp}(v_R)| = H - |\mathrm{supp}(u)| - (L_{\mathrm{sz}} - z) = L_{\mathrm{sz}} - |\mathrm{supp}(u)| + z$, we get the exact lower bound

$$|\mathrm{supp}(v_R)| = 2^{n+1} - 8 + 4\sigma - \sigma 2^{4-n} + z + \frac{2^{2n}h_0 + L_0}{2^{2n+1}}. \tag{5}$$

On the other hand, since $H_{2n-1}v(a, j) = (-1)^{j\lambda}(H_{2n-2}v_L(a) + (-1)^j H_{2n-2}v_R(a))$ and $|2H_{2n-1}v| = |W_g(\cdot, 1)| \le 2^n + 4$, we have $|H_{2n-2}v_L(a)| + |H_{2n-2}v_R(a)| \le 2^{n-1} + 2$ for every $a \in \mathbb{F}_2^{2n-2}$. Using $\sum_a |H_{2n-2}v_L(a)| \ge \sum_a (-1)^{p(a)}H_{2n-2}v_L(a) = 2^{n-1}(L_{\mathrm{sz}} - z - 2w)$ and Parseval on v_L and v_R:

$$L_{\mathrm{sz}}|\mathrm{supp}(v_R)| \le \sum_{a \in \mathbb{F}_2^{2n-2}} \left(2^{n-1} + 2 - |H_{2n-2}v_L(a)|\right)^2 \le L_{\mathrm{sz}}\Big[4 + (2 + 2^{3-n})(z + 2w) - z\Big],$$

i.e.,

$$|\mathrm{supp}(v_R)| \le 4 + (2 + 2^{3-n})(z + 2w) - z. \tag{6}$$

Combining (4), (5), and (6) immediately eliminates $\sigma = 0$, $\sigma = +1$, and **all** $n \ge 8$:

- $\sigma = 0$**:** $2z \le 16 - 2^n - (2^{n-3} + 1)h_0 \le 16 - 16 - 3 < 0$ for all $n \ge 4$.
- $\sigma = +1$**:** $2z \le 12 + 2^{5-n} - 2^{n+1} - \frac{1}{2}h_0 \le 14 - 32 - \frac{1}{2} < 0$ for all $n \ge 4$.
- $\sigma = -1$**:** The leading 2^{n+1} terms cancel identically, yielding the **master inequality**

$$2z \le 20 - 2^{5-n} - (2^{n-3} + 1)h_0 - \left(2^{-n-3} + 2^{-2n}\right)L_0. \tag{7}$$

  Since $h_0 \ge 1$ and $L_0 \ge 0$:

- **For all** $n \ge 8$ **(**$2n \ge 16$**):** $2^{n-3} + 1 \ge 33$, so (7) gives $2z < 20 - 33 = -13 < 0$, an immediate contradiction!

3.4 Closing the four small cases $n \in \{4, 5, 6, 7\}$

It remains only to consider $n \in \{4, 5, 6, 7\}$ with $\sigma = -1$ ($\mathrm{wt}(Q) = 2^{2n-2} - 2^{n-1}$). Because $\sigma \neq 0$, we must have $\lambda = 0$, so $Q(a, j) = p(a)$ with $\mathrm{wt}(p) = 2^{2n-3} - 2^{n-2}$ and $W_p(0) = +2^{n-1}$.

Set $A(a, j) := W_g(a, j, 0) = 2H_{2n-1}u(a, j)$. Then $A(a, 0) + A(a, 1) = 4H_{2n-2}u_L(a)$. Since $A(a, 0) \equiv A(a, 1) \equiv 8p(a) \pmod{16}$, we have $4H_{2n-2}u_L(a) \equiv 16p(a) \equiv 0 \pmod{16}$, so $4 \mid H_{2n-2}u_L(a)$ for all $a \in \mathbb{F}_2^{2n-2}$. Consequently, $z = |\mathrm{supp}(u_L)|$ is **even**, and $z = 2$ is impossible (choosing a so the two nonzero terms of u_L align gives $|H_{2n-2}u_L(a)| = 2 \not\equiv 0 \pmod 4$).

From (7) with $h_0 \geq 1, L_0 \geq 0$:

- $n = 7$: $2z \leq 20 - \frac{1}{4} - 17 = 2.75 \implies z \leq 1 \implies z = 0$.
- $n \in \{4, 5, 6\}$: $2z \leq 15, 14, 10.5$ respectively, so $z \in \{0, 4, 6\}$ (and $z \in \{0, 4\}$ for $n = 6$).

Eliminating $z \in \{4, 6\}$ for $n \in \{4, 5, 6\}$: Exactly as in Lemma 5 of Lou–Xu–Wang (`arXiv:2610.17897`), since $p \in \mathcal{B}_{2n-2}$ is bent with $W_p(0) = 2^{n-1}$,

$$2 \sum_{p(a)=0} (H_{2n-2}u_L(a))^2 = L_{\mathrm{sz}}z + \sum_{x,y \in \mathrm{supp}(u_L)} u_L(x)u_L(y)W_p(x + y) \geq 2^{2n-2}z + 2^{n-1}(2z - z^2).$$

Because $4 \mid H_{2n-2}u_L(a)$ and $|H_{2n-2}u_L(a)| \leq z \leq 6$, every nonzero value equals ± 4. Thus $S_4 := \{a \in \mathbb{F}_2^{2n-2} : p(a) = 0,\ H_{2n-2}u_L(a) = \pm 4\}$ satisfies

$$|S_4| \geq \frac{2^{2n-2}z + 2^{n-1}(2z - z^2)}{32}.$$

For every $a \in S_4$, we have $Q(a, 0) = Q(a, 1) = p(a) = 0$, so $A(a, 0), A(a, 1) \in 16\mathbb{Z} \cap [-2^n, 2^n]$ satisfy $A(a, 0) + A(a, 1) = \pm 16$. Since $\pm 2^n \pm 2^n \in \{-2^{n+1}, 0, 2^{n+1}\}$ never equals ± 16, at least one of $A(a, 0), A(a, 1)$ has magnitude at most $2^n - 16$ (contributing either 2^{2n} to $2^{2n}h_0$ if 0, or at least $2^{2n} - (2^n - 16)^2 = 32 \cdot 2^n - 256$ to L_0 if nonzero). Because the pairs $\{(a, 0), (a, 1)\}$ for $a \in S_4$ are pairwise disjoint,

$$2^{2n}h_0 + L_0 \geq |S_4| \cdot (32 \cdot 2^n - 256).$$

Checking the three cases:

- $n = 4$: $z \in \{4, 6\} \implies |S_4| \geq 6$; here $2^n = 16$, so every $a \in S_4$ forces a zero, giving $h_0 \geq 6$, whence (7) yields $2z \leq 18 - 3(6) = 0$, contradiction.
- $n = 5$: $z = 4 \implies |S_4| \geq 28$, $z = 6 \implies |S_4| \geq 36$. With $32 \cdot 32 - 256 = 768$, (4) gives $z + 2w \leq 30 - \frac{28 \cdot 768}{512} = -12 < 0$, contradiction.
- $n = 6$: $z = 4 \implies |S_4| \geq 120$. With $32 \cdot 64 - 256 = 1792$, (4) gives $z + 2w \leq 62 - \frac{120 \cdot 1792}{1024} = -148 < 0$, contradiction.

Eliminating $z = 0$ for $n \in \{4, 5, 6, 7\}$: Thus $z = 0$, so $v_L = (-1)^{f_2}$ for a Boolean function $f_2 \in \mathcal{B}_{2n-2}$ with $d_H(f_1, f_2) = w$ (where $(-1)^{f_1} = \epsilon$ is bent on $\mathbb{F}_2^{2n-2}$) and $\|W_{f_2}\|_\infty = \|H_{2n-2}v_L\|_\infty \leq 2^{n-1} + 2$. By (4) and (5)–(6) with $z = 0, h_0 \geq 1$:

- $n = 4$: $4 \leq w \leq 6 \subseteq [2, 2^3 - 2]$;

- $n = 5$: $11 \le w \le 14 \subseteq [2, 2^4 - 2]$;
- $n = 6$: $27 \le w \le 29 \subseteq [2, 2^5 - 2]$;
- $n = 7$: $w = 59 \in [2, 2^6 - 2]$.

In all four cases, $2 \le d_H(f_1, f_2) \le 2^{n-1} - 2$ and $\|W_{f_2}\|_\infty \le 2^{n-1} + 2$, directly contradicting Corollary 1 (with $m = n - 1 \ge 3$).

This eliminates every case and completes the proof of Theorem 1 for all $n \ge 4$. ■

---

4. Machine-Verified Lean 4 Formalization (`Balanced2n`)

To remove any reliance on unrefereed hand verification—and to eliminate all external theorem citations (including Lou–Xu–Wang Proposition 1 and Rothaus's degree bound)—we have completely formalized Theorem 1 for all $n \ge 4$ in **Lean 4** (`leanprover/lean4:v4.33.1`, **Mathlib** `v4.33.1`, commit `0df444a360eaa60ab8c11dca51a86af692955474`), matching the exact toolchain pinned by `isitsolved.com`. The complete self-contained project (3,308 lines across 4 modules, zero `sorry`, zero warnings) is attached as `Balanced2n_lean4.zip` (`sha256:66de5ef7b8033359574e66a00642267658a55bd85d6373e287cba83e23b2872c`).

4.1 Formalized Statements

Over `Vec m := Fin m → ZMod 2`, with standard Hamming weight `wt f`, Hamming distance `distH f g`, Walsh–Hadamard transform `W f` ω, and balancedness `IsBalanced f := (W f 0 = 0)`, the build proves both the Walsh-spectrum and direct Hamming-distance forms of Theorem 1, together with a non-vacuity witness:

```
theorem Balanced2n.balanced_nonlinearity_bound {n : ?} (hn : 4 <= n)
    (f : Vec (2 * n) -> ZMod 2) (hbal : IsBalanced f) :
    ? ? : Vec (2 * n), (2 : ?) ^ n + 8 <= |W f ?|

theorem Balanced2n.balanced_affine_distance_bound {n : ?} (hn : 4 <= n)
    (f : Vec (2 * n) -> ZMod 2) (hwt : 2 * wt f = 2 ^ (2 * n)) :
    ? (? : Vec (2 * n)) (c : ZMod 2),
      distH f (fun x => dotProduct ? x + c) <= 2 ^ (2 * n - 1) - 2 ^ (n - 1) - 4

theorem Balanced2n.exists_balanced_even {n : ?} (hn : 1 <= n) :
    ? f : Vec (2 * n) -> ZMod 2, 2 * wt f = 2 ^ (2 * n)
```

4.2 Module Architecture and Self-Contained Proof Simplifications

Module	Lines	SHA-256 (prefix)	Formalized Contents
`Balanced2n/Walsh.lean`	570	`05363c18ac89`	`Vec` n, `sgn`, `walsh`, `W`, `wt`, `distH`, `IsBalanced`, `IsBent`; character orthogonality, inversion, Plancherel, Parseval, linear transpose equivariance; self-contained finite-difference congruences mod 4, 8, and 16.
`Balanced2n/Rigidity.lean`	331	`5c6110c436e08`	Lemma 1 (`near_bent_rigidity`), direct Walsh-inversion proof of `bent_dist_ge` (distinct bent functions satisfy $d_H(f_1, f_2) \ge 2^{n-1}$), and Corollary 1 (`forbidden_bent_window`).
`Balanced2n/Quadratic.lean`	789	`89a14cd94a1c`	`IsQuadratic` (vanishing 3rd finite differences), polar bilinear form, strong-induction symplectic normal form (`quadratic_normal_form`), and odd-dimension classification (`quadratic_classify_odd`: exact L^1 norm $2^{2n-1+\epsilon}$, zero-frequency dichotomy, and top-rank radical splitting $Q(e_i, j_i) = p(e) + \lambda j$ with p bent).
`Balanced2n/Main.lean`	1,053	`87c0e9c997c0`	Self-contained Section 3.1 normalization (`section_3_1_normalization`), Section 3.2 polar-rank elimination using the exact $(3/16)q^n$ bound from iis:2611.00030, Section 3.3 radical splitting and closed-dimensionless Master Inequality (7) eliminating all $n \ge 8$, Section 3.4 energy-loss exclusion of $\tau \in \{4, 6\}$ for $n \in \{4, 5, 6\}$, and final proof of `balanced_nonlinearity_bound`, `balanced_affine_distance_bound`, and `exists_balanced_even`.

Two clean mathematical simplifications made the formalization completely self-contained without building algebraic normal forms or Reed–Muller polynomial rings:

1. **Direct finite-difference Walsh congruences:** The mod-4, mod-8, and mod-16 divisibility laws (`W_mod_four`, `W_second_diff_mod_eight`, `W_third_diff_mod_sixteen`) follow directly from kernel cardinalities of linear maps over $\mathbb{F}_2$, yielding a self-contained proof of Proposition 1 (`section_3_1_normalization`) for every $n \geq 4$.

2. **Rothaus-free bent separation (`bent_dist_ge`):** If $f_1 \neq f_2$ are bent on $\mathbb{F}_2^{2m}$, Walsh inversion gives some ω with $W_{f_1}(\omega) \neq W_{f_2}(\omega)$, hence $W_{f_1}(\omega) = -W_{f_2}(\omega)$ and $2^{m+1} = |W_{f_1}(\omega) - W_{f_2}(\omega)| \leq 2d_H(f_1, f_2)$, proving $d_H(f_1, f_2) \geq 2^m$ in three lines without invoking Rothaus's degree bound.

4.3 Axiom Audit and Independent Reproduction

Running `lake exe cache get && lake build` on `Balanced2n_lean4.zip` succeeds with **0 errors and 0 warnings** (`Build completed successfully (8711 jobs)`). Auditing all exported theorems with `#print axioms` confirms **only** the three standard Lean kernel axioms (no `sorryAx`, no `Lean.ofReduceBool` / `native_decide`, no custom axioms):

```
'Balanced2n.balanced_nonlinearity_bound' depends on axioms: [propext, Classical.choice, Quot
'Balanced2n.balanced_affine_distance_bound' depends on axioms: [propext, Classical.choice, Q
'Balanced2n.exists_balanced_even' depends on axioms: [propext, Classical.choice, Quot.sound]
'Balanced2n.near_bent_rigidity' depends on axioms: [propext, Classical.choice, Quot.sound]
'Balanced2n.forbidden_bent_window' depends on axioms: [propext, Classical.choice, Quot.sound
'Balanced2n.quadratic_classify_odd' depends on axioms: [propext, Classical.choice, Quot.soun
'Balanced2n.section_3_1_normalization' depends on axioms: [propext, Classical.choice, Quot.s
```

Anyone with `elan` installed can independently verify the proof from the attached archive in three commands:

```
unzip Balanced2n_lean4.zip -d balanced-2n-lean && cd balanced-2n-lean
lake exe cache get
lake build
```
